Microfluidic devices are well known in the field of analytical chemistry for performing a variety of sample-processing tasks, such as mixing, reacting, analyzing and detecting the presence of specific substances in a variety of chemical and biological samples. The analytes are generally either suspended in a fluid, such as a liquid or gas, or are contained in a substrate, such as a membrane or microparticle, which contacts a fluid. Examples of chemical and biological samples which are frequently analyzed by microfluidic devices include food samples, environmental samples, human or animal body samples, and industrial waste samples. In the analytical methods often used with microfluidic devices, the device is typically loaded with a sample, often in the form of a liquid, and then is exposed to the sample through an aperture or other port through which a fluid (e.g., a gas or liquid) is subsequently passed or to which the fluid passes through during the analysis. Examples of methods used to analyze a sample in a microfluidic device include chromatographic separation, electrophoresis, electrochemical detection, evanescent wave detection, fluorescence detection and optical detection. Often, the sample is initially exposed to a fluid that is subsequently passed through a port of the device to a second fluid. The first and second fluids are often miscible but may also be immiscible. For example, one fluid may dissolve in or otherwise mix with the sample. Such mixing facilitates the analysis by allowing for further chemical reactions or for the complete or partial dissolution of the sample. In certain microfluidic devices, the sample and fluids are passed through the device by controlling the flow of the fluid through the aperture. This requires that the aperture be aligned with one or more ports or channels which directs the fluid flow f678ea9f9e
